ABSTRACT

Pyometra, the accumulation of purulent material in the uterine cavity, represents 0.038% of gynecologic admissions; its etiology is impaired drainage of the uterine cavity (1). It is uncommon in premenopausal age and occurs mainly in older and postmenopausal women. The classical clinical signs of pyometra are vaginal discharge, postmenopausal bleeding, and lower abdominal pain (2). The etiology of the uterus perforation is blockage of natural drainage due to stenotic cervix, which results in a degenerative or necrotic change in the pyometra (3, 4). This perforation is related to diffuse peritonitis and causes acute surgical abdomen with free intra-abdominal air.

Herein, we report an a patient presenting with abdominal pain and generalized peritonitis caused by perforation of pyometra without malignancy.

INTRODUCTION

Pyometra, the accumulation of purulent material in the uterine cavity, is a rare gynecological condition whose etiology is impaired drainage of the uterine cavity (1). It is uncommon in premenopausal age and occurs mainly in older and postmenopausal women. The classical clinical signs of pyometra are vaginal discharge, postmenopausal bleeding, and lower abdominal pain (2). The etiology of the uterus perforation is blockage of natural drainage due to stenotic cervix, which results in a degenerative or necrotic change in the pyometra (3, 4). This perforation is related to diffuse peritonitis and causes acute surgical abdomen with free intra-abdominal air.

CASE PRESENTATION

An 87-year-old woman was admitted to our emergency department with abdominal pain, fever, and vomiting lasting approximately two days. The patient had a history of diabetes and hypertension, and the patient was immobilized and permanently bedridden for two years due to pelvic trauma and poor general condition. Her gynecological history was unremarkable, and she had no vaginal bleeding or increased discharge. The results of a physical examination revealed rebound tenderness, muscular rigidity in the lower abdomen, and distention. Her body temperature was 38.4 °C, her pulse rate was 112 beats/min, and her blood pressure was 140/70. Laboratory studies on admission demonstrated a white cell count of 5000/mm³ with 83.6% neutrophilia and hemoglobin 11.3. A plain chest x-ray showed no free air under the diaphragm and no intestinal obstruction sign. Ultrasonography demonstrated free fluid at the iliac fossa/pelvis; percutaneous aspiration revealed that this fluid was purulent, with no relationship to gastrointestinal tract perforation or bile fistula.

A computed tomography (CT) scan of the abdomen with intravenous contrast showed a large amount of free fluid in the abdominal cavity and a uterine myoma with a diameter of 77x58 mm (Figure 1a). Computed tomography (CT) with an intravenous injection of contrast material showed an enlarged and distended uterus with a breach at the uterine fundus. A dilated endometrial cavity with hypodense fluid collection was suggestive of pyometra. Due to perforated pyometra, multiple pelvic and intra-abdomi-
nal fluid collections were observed in the CT scan (Figure 1b). The patient underwent emergency laparotomy due to acute abdomen. During the laparotomy, a 2x1 cm perforation was seen at the fundus of the uterus (Figure 2). There was one liter of purulent material in the abdomen. The patient underwent total abdominal hysterectomy with bilateral salpingo-oophorectomy. A culture of the pus grew *Escherichia coli*. Histopathological examination revealed degenerative uterine myoma with no evidence of malignancy. Pathological results indicated myometrial suppurative inflammation with neutrophilia and necrosis (Figure 3). Postoperatively, the patient was monitored in the surgical intensive care unit, as septic shock required inotropic support for five days. The patient had wound problems that required vacuum-assisted closure; after that, she recovered and was discharged at the 28th postoperative day after providing informed consent.

**DISCUSSION**

Pyometra is a rare event; however, it must be considered when investigating acute abdomen etiology, and emergency physicians must be aware of ruptured pyometra. Although it is a rare condition, it carries morbidity and mortality risks. In the English literature between 1985 and 2015, only 68 cases of pyometra perforation were reported; 38 of these cases did not originate from a malignancy, similar to our report (5). Because of canal stenosis, the uterus enlarges progressively with degenerative changes until the uterine contents finally spill into the abdominal cavity with perforation (6). Pyometra is related to a general etiology of benign or malignant gynecologic tumors, radiation cervicitis, atrophic cervicitis, congenital anomalies, intrauterine devices, and traumatic damage to the cervix (7). If the pyometra is related to malignancy and perforation of the uterus, the prognosis is very poor and bears significant morbidity and mortality risks (8).

In the literature, the median age of ruptured pyometra was 73.8; in geriatric women with concomitant diseases, the mortality rate is 25% to 40% (5, 6, 9). For these septic geriatric patients, emergency conditions and surgery require resuscitation and management of respiration as well as circulation in the intensive care unit and long hospital stays, as in the case of the patient reported in this study. Immunocompromised state has been documented as a high risk for perforation; these patients also have a higher mortality risk (6).

The clinical signs and emergency department admission of pyometra patients are due to acute abdomen. However, a significant percentage of patients with unruptured pyometra are asymptomatic (10). Additionally, due to the nonspecific symptoms associated with rupture, early and accurate diagnosis of perforation is limited. Accurate preoperative diagnoses were obtained for only 21% of ruptured pyometra patients (5). Acute abdomen symptoms such as abdominal pain, vomiting, and fever predominate at admission, while gynecological symptoms such as vaginal bleeding or discharge occur in fewer than 10% of cases (11, 12). The initial diagnosis of the disease can be mistaken as gastrointestinal perforation because of the pneumoperitoneum; however, definitive diagnosis of the disease is sometimes obtained intra-operatively (13). Radiological findings of contrast-enhanced CT are important...
in diagnosis, along with findings of the presence of fluids in the uterus, defects of the uterine wall, and intraabdominal fluid collection (14). Free air in the peritoneal cavity and the uterine cavity due to gas-forming organisms are reasons to suspect ruptured pyometra (5). Some reporters illustrate the importance of transvaginal ultrasound to accurate preoperative diagnosis (5, 11). In the absence of gynecological symptoms in most cases, sonography may be adequate to illustrate fluid accumulation in the cavity (11).

Pyometra involves abscess formation; drainage and evacuation of the uterine cavity is the main treatment protocol, along with placing a drain in the cavity and dilating the cervical canal (8, 15). Persistent pyometra requires repeated drainage and dilatation. In cases of perforation, hysterec- tomy is the treatment choice, with peritoneal lavage and abscess drainage (2). In some reports, the authors suggest management by total abdominal hysterectomy with bilateral salpingo-oophorectomy; however, subtotal or supravaginal hysterectomy, drainage alone, and surgical closure of the perforated uterine wall have been reported in different cases (6, 11).

The pathological results of pyometra are related to the etiology of the disease. Benign tumors, spread of malignance from the endocervix, and endometrial cancer are usually associated with pyometra, and xanthogranulomatous inflammation is also reported in surgical specimens (16, 17). The necrotic nature of the uterine tissue with pyometra sometimes requires frozen section examination.

Treatment of pyometra includes broad spectrum antibiotics against aerobic and anaerobic bacteria. Occasionally, upon microbiological examination, Escherichia coli, Bacteroides fragilis, Streptococcus spp. and Pseudomonas aeruginosa are isolated (18, 19). Similar to published reports, in our case, culture of the pus grew Escherichia coli; this is the most common infectious agent. Source control with surgery is important in the resuscitation of septic conditions due to peritonitis.

CONCLUSION
Pyometra perforation is a rare cause of acute abdomen. In older patients with concomitant diseases, immediate laparotomy, peritoneal lavage, and hysterectomy are associated with important morbidity and mortality risks. Sepsis, septic shock, and multiple organ failure may be encountered in clinical presentation due to bacteremia. These acute conditions require intensive care. Accurate and early diagnosis with proper treatment can reduce the mortality and morbidity of pyometra.
