ABSTRACT

Objective: Despite the recent use of computed tomography scan and diagnostic laparoscopy, acute appendicitis is still highly misdiagnosed. Timely diagnosis of acute appendicitis is more crucial in children and elderly patients because of vague symptoms and rapid progression to perforation in these age groups, which may result in high rates of morbidity and mortality. The aim of the present study was to find the diagnostic values of procalcitonin and interleukin 6 (IL-6) for diagnosing acute appendicitis in our center.

Material and Methods: Patients who were suspected of acute appendicitis and referred to the emergency department of a tertiary care urban hospital in 2016 were enrolled in the study. A 5 mL blood sample was obtained from each patient before appendectomy and was examined for procalcitonin and IL-6. Then the resected specimen of the appendix was studied by a pathologist, and a definite diagnosis was made.

Results: Eighty patients including 53 (66.3%) men who underwent appendectomy were enrolled in the study. The diagnosis of acute appendicitis was histopathologically confirmed in 60 (75%) patients including 18, 20, and 22 patients with inflammatory, suppurative, and gangrenous/perforated appendicitis, respectively. The sensitivity and specificity of procalcitonin versus IL-6 for diagnosing acute appendicitis were 65% and 80% vs. 76% and 55%, respectively. The sensitivity and specificity of concurrent procalcitonin and IL-6 for diagnosing acute appendicitis were 95% and 55%, respectively.

Conclusion: Our study suggests that parallel measurement of procalcitonin and IL-6 decreases unnecessary negative appendectomies.

Keywords: Appendicitis, interleukin 6, procalcitonin

INTRODUCTION

Appendicitis is the most common cause of surgery of the abdomen with an incidence rate of 11 in 10,000 annually, and it most commonly occurs in the second to fourth decade of life especially in young adults (1,2). Timely diagnosis of acute appendicitis is crucial especially in children and elderly patients because of vague symptoms and rapid progression to perforation in these age groups, which may result in high rates of complications including wound infection, intra-abdominal abscess formation, and mortality (3,4). Despite the recent use of computed tomography scan and diagnostic laparoscopy, acute appendicitis is still highly misdiagnosed at a rate of 15%, with the highest number of negative appendectomy seen in elderly women (5). Hence, additional preoperative testing may be helpful for the timely diagnosis of acute appendicitis. Although the role of the measurement of inflammatory cytokines, such as procalcitonin, interleukin 6 (IL-6), and C-reactive protein, which are involved in acute and chronic inflammatory responses in addition to the measurement of white cell count and bilirubin for diagnosing acute appendicitis, has been investigated in few studies, the results have varied with no consensus about the best test (6,7).

The aim of the present study was to find the diagnostic values of procalcitonin and IL-6 in the diagnosis of acute appendicitis and their associations with the severity of the disease in our center.
MATERIAL and METHODS

Patient Selection

In this prospective study, patients who were suspected of acute appendicitis and referred to the emergency department of a tertiary care urban hospital in 2016 were enrolled in the study. Patients with an Alvarado score of > 5 or in whom diagnosis of acute appendicitis was documented using computed tomography scan were included into the study. Exclusion criteria comprised patients with a history of autoimmune disease; who underwent transplantation; receiving immunosuppressive, antibiotic, and/or immunomodulator drugs; who were in sepsis; or who were markedly overweight with a body mass index > 25. All patients were visited and examined by the same surgeon.

The research was conducted according to the principles of the World Medical Association Declaration of Helsinki “Ethical Principles for Medical Research Involving Human Subjects” (amended in October 2013). Written informed consent was obtained from all participants. Medical University Ethics Committee approved the study.

Study Protocol

A 5 mL blood sample was obtained from each patient before appendectomy. No antibiotic or antipyretic drugs were administered before sampling. Serum samples were stored at -20°C, and all measurements were performed under similar conditions on the same day. The measurement of procalcitonin and IL-6 was performed using enzyme-linked immunosorbent assay Human Procalcitonin (Eastbiopharm, China) and AviBion Human IL-6 (Or-genium, Finland) kits, respectively. Serum levels of > 0.5 ng/mL for procalcitonin and 5 pg/mL for IL-6 were considered as positive in our study. A pathologist examined the resected specimen of the appendix, and a definite diagnosis was made as normal appendix, inflammatory defined as infiltration of inflammatory cells, suppurative defined as infiltration of inflammatory cells with destruction of the appendiceal wall, with no evidence of abscess or perforation, and gangrenous and/or perforated appendicitis defined as infiltration of inflammatory cells, necrotic appendiceal wall, and macroscopic periappendiceal abscess and/or perforation.

Statistical Analyses

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 20.0 (IBM Corp., Armonk, NY, USA). Qualitative and quantitative data were compared using the Fischer’s exact and independent t tests, respectively. A p value < 0.05 was considered as statistically significant.

RESULTS

Eighty patients including 53 (66.3%) men who underwent appendectomy were enrolled in the study. The frequency of patients in the 0-20, 21-40, 41-60, and older than 60 years old age groups were 30 (37.5%), 39 (48.8%), 6 (7.5%), and 5 (6.2%) patients, respectively. The diagnosis of acute appendicitis was histopathologically confirmed in 60 (75%) patients including 18, 20, and 22 patients with inflammatory, suppurative, and gangrenous/perforated appendicitis, respectively.

Figure 1 shows the frequency of positive procalcitonin or IL-6 in patients with the aforementioned different histopathology diagnoses. The sensitivity and specificity of procalcitonin for diagnosing acute appendicitis were 65% and 80%, respectively, with positive and negative likelihood ratios of 3.25 and 0.43, respectively, and positive and negative predictive values of 90% and 43%, respectively. In addition, the sensitivity and specificity of IL-6 for diagnosing acute appendicitis were 76% and 55%, respectively, with positive and negative likelihood ratios of 1.7 and 0.42, respectively, and positive and negative predictive values of 83% and 44%, respectively. On the other hand, the sensitivity and
Similarly, in a recent systematic review by Acharya et al., the pooled sensitivity and specificity of serum procalcitonin for diagnosing acute appendicitis were 68% and 52%, respectively, and for diagnosing perforated appendicitis were 91% and 67%, respectively (13). Similar to our results, some other studies have suggested that the measurement of procalcitonin is more sensitive for diagnosing perforated appendicitis, whereas it has less accuracy for diagnosing uncomplicated appendicitis (14,15).

During acute appendicitis, other proinflammatory cytokines, especially IL-6 as mediators of fever and acute phase reactions, are secreted due to the inflammatory process and neutrophil recruitment following the invasion of bacteria to the appendix (16, 17). In the present study, the sensitivity and specificity of serum IL-6 for diagnosing acute appendicitis were 76% and 55%, respectively, and for diagnosing perforated appendicitis were 91% and 37%, respectively. Similarly, previous studies have shown that the measurement of IL-6 is associated with high sensitivity and low specificity for diagnosing acute appendicitis. Ozguner et al. have shown that the serum level of IL-6 is significantly lower in children with negative appendectomy than in children with complicated or uncomplicated appendicitis, suggesting that the measurement of IL-6 is helpful in reducing the number of negative appendectomies (18).

In the study by Gürleyik et al., the sensitivity and specificity of IL-6 are 84% and 46%, respectively, and a marked elevation of IL-6 level has been reported in patients with perforated appendicitis (19). In the aforementioned systematic review, similar to our study, the pooled sensitivity and specificity of IL-6 for diagnosing acute appendicitis have been found as 73% and 72%, respectively, and for diagnosing perforated appendicitis as 79% and 63%, respectively. Moreover, the overall performance of IL-6 has been reported to be superior to procalcitonin, especially in terms of cost, sensitivity, and prediction of perforation. However, IL-6 is not specific especially for diagnosing complicated appendicitis and associated with higher time spent for obtaining the result than procalcitonin (13). As previously mentioned, the measurement of procalcitonin was associated with low sensitivity and high specificity, whereas IL-6 was associated with high sensitivity and low specificity for the diagnosis of acute appendicitis. The total sensitivity and specificity of measurement of these two biomarkers combined were 95% and 55%, respectively, for diagnosing of acute appendicitis.

CONCLUSION

Our study suggests that the measurement of combining procalcitonin and IL-6 can provide beneficial evidence for superior decision-making, and owing to high sensitivity, negative results of each of these biomarkers may assist in ruling out acute appendicitis and reducing the number of negative appendectomies.

**Ethics Committee Approval:** Ethics committee approval was received for this study from the Ethics Committee of Hamadan University of Medical Sciences.

**Informed Consent:** Written informed consent was obtained from patients who participated in this study.

**Peer-review:** Externally peer-reviewed.

**Conflict of Interest:** The authors have no conflicts of interest to declare.

**Financial Disclosure:** The authors declared that this study has received no financial support.

ÖZET

Giriş ve Amaç: Son yıllarda artan bilgisayarlı tomografi ve tanısal laparoskopi kullanımlarına rağmen akut apandisit hala yüksek oranda yanlış tanı almaktadır. Bu yüzden gruptan belirli semptomlar ve perforasyona çabuk ilerlemesi sebebiyle yüksek oranda morbidite ve mortalite ile sonuçlanırsa, akut apandisit tanısının çoğukluk ve ileri yaş hastalarda zamanda konumsuz olması önemi altına çekmektedir. Bu çalışmanın amacı, merkezimizde acil servise sevk edilen acil servis hastaları ile ilgili prokalsitonin ve interlökin 6 (IL-6) degerlerinin analiz edilmesi ve bu değerlerin akut apandisit tanısını desteklemek için kullanılabileceğinin gösterilmesidir.

Gereç ve Yöntem: Çalışmamız, 2016 yılında akut apandisit şüphesi ile üçüncü basamak şehir hastanesi acil servisine sevk edilen hastalar dahil edilmiştir. Appendektomi sonrası tüm hastaların 5 mL kan örnekleri alınarak prokalsitonin ve IL-6 incelemeleri yapılmıştır. Daha sonra, appendektomisi yapılan hasta kesin tanısı konuldu. Prokalsitonin ve IL-6 değerlerinin akut apandisit tanısının konumsal ve geçersiz olduğuna dair etkisi incelendi.

Bulgular: Eşit ışık (%66.3) ve emekli (20%) ile ilgili pozitif prokalsitonin ve interlökin 6 değerlerinin (IL-6) değerleri alta düştü. Prokalsitonin ve IL-6 değerlerinin akut apandisit tanısı konumsal ve geçersiz olduğuna dair etkisi incelendi.

Sonuç: Çalışmamız, akut apandisit tanısının konumsal ve geçersiz olduğuna dair etkisi incelendi. Prokalsitonin ve IL-6 değerlerinin akut apandisit tanısı konumsal ve geçersiz olduğuna dair etkisi incelendi.

Anahtar Kelimeler: Akut apandisit, prokalsitonin, interlökin 6
